In fact, many people were so frightened of terrorism that they actually refused to leave their homes, and the number of people who became a victim of a terror attack increased by more than 25 percent. A number of people who had been victims of terror attacks suffered from Post Traumatic Stress Disorder (PTSD), and some of those were forced to leave the area where the attacks occurred and move to a different place. The 3D seismic images can be acquired using either a move-out (MO) method or an angle of arrival (AoA) method. 3D seismic images can also be generated from sparse data, or from data for which there are not enough sensors to generate an entire image. These sparse images are used in the field for the exploration of various subsurface formations. An AoA method generates 3D seismic images from data acquired using transducers that emit and/or detect acoustic waves. One of the transducers of the transducer array, e.g., an ocean bottom seismic sensor ("OBS"), is typically spaced apart from a seafloor location ("imaging location" or "OBS location") by a distance that is greater than a wavelength of the acoustic waves (e.g., 40 km). Typically, the waves from the OBS can be traced back to one or more energy sources, e.g., seismic source(s), and back to the OBS location. The relative time of arrival of the waves from the energy source to the OBS can be used to estimate the depth of the seabed below the OBS location. Thus, depth information about the local ocean bottom is known. A single source may be used, e.g., a high frequency seismic source such as air guns or explosive charges, or multiple sources may be used, e.g., a marine seismic source towed behind a vessel. A fixed-angle migration method is known for generating a first subset of the 3D seismic images. A second subset of the 3D seismic images (AoA subset) is generated by adapting the migration method, e.g., by using previously obtained depth information.
